Abstract

The current study aimed to explore the effects of integrating a self-regulated learning approach on self-efficacy in vocabulary learning. A group of 115 English as a Foreign Language (EFL) learners from a university in Japan participated in this longitudinal study. The participants were assigned as the treatment group, the contrast group 1, and the contrast group 2. Only the treatment group received the intervention based on the self-regulated learning approach. The participants completed a questionnaire on self-efficacy in vocabulary learning three times and a vocabulary test twice. Multilevel analysis of change was employed to examine the trajectories of change in the participants’ self-efficacy over the measurement occasions. The gain scores in the vocabulary test were submitted to analysis of variance. The results showed that the treatment group showed a steady increase in self-efficacy and vocabulary knowledge compared with the other two contrast groups. The findings from the current study provide empirical evidence suggesting that through a self-regulated learning approach, it might be possible to enhance self-efficacy, which in turn may contribute to the development of vocabulary knowledge.

1 Background

It is a well-known fact in vocabulary research and instruction that teachers cannot teach all the words learners may need to know. In fact, Nation (2008) argues that in a well-designed vocabulary development program, the teacher’s jobs “in order of importance are planning, strategy training, testing and teaching vocabulary” (p. 1). Teaching comes at the end of the list because vocabulary teaching tends to be inefficient considering that (a) there are simply too many words to deal with, (b) the rate of teaching words has to be slow, (c) the amount of learning is low, and (d) using word cards, or flash-card programs, can result in close to 100% learning (Nation, 2012).

As learners have to learn vocabulary independently and outside the classroom in most instances, vocabulary learning strategies are of particular importance. This is also why Nation (2008) regards strategy training to be the second most important job in vocabulary teaching. The purpose of strategy training is to get the learners to become independent and autonomous in their vocabulary learning (Nation, 2008, p. 4). A number of studies on vocabulary learning strategies instruction have been conducted with this goal in mind (e.g., Mizumoto & Takeuchi, 2009; Rasekh & Ranjbary, 2003; Zaki & Ellis, 1999). They have generally reported positive results for strategy instruction, and thus practitioners are now in a better position to incorporate strategy training in their vocabulary teaching.
In recent years, the concept of language-learning strategies has expanded into a more extensive notion of self-regulated learning, partly in response to a wave of criticism directed at the paucity of rigid theoretical underpinnings (see Cohen & Macaro, 2007; Dörnyei, 2005; Tseng, Dörnyei, & Schmitt, 2006 for details). Self-regulated learning, or self-regulation, has been researched mainly within the field of educational psychology. Although several theories of self-regulation exist, Zimmerman’s social-cognitive model of self-regulation (1989) suggests that “self-regulation involves learners who proactively direct their behavior or strategies to achieve self-set goals. They also rely on affective, cognitive, motivational, and behavioral feedback to modify or adjust their strategies and behaviors when unable to initially attain their goals” (Cleary & Zimmerman, 2004, p. 538).

In theory, engaging in the cyclical model of self-regulated learning will enhance self-efficacy as “(s)elf-regulation affects motivation, emotions, selection of strategies, and effort regulation and leads to increases in self-efficacy and improved academic achievement” (Bembenutty, 2011, p. 4). However, no study to date has investigated the effects of self-regulated learning on self-efficacy in vocabulary learning. In the current study, therefore, the effects of integrating a self-regulated learning approach into regular English courses were examined. The research question of the current study was as follows: will self-efficacy for vocabulary learning be enhanced by integrating a self-regulated learning approach?

2 Method

2.1 Participants

The study was conducted during the two semesters in the academic year 2012. The participants were three intact classes of Japanese university English as a Foreign Language (EFL) learners at a private university in western Japan (humanities or engineering majors; aged 18–20). They were first-year students enrolled in a compulsory English course at their university.

The three groups were assigned as (a) the treatment group, (b) the contrast group 1, and (c) the contrast group 2. The participants in the contrast group 1 were of a lower level of English proficiency, and those in the contrast group 2 had the highest level of English proficiency of the three groups. After the list-wise deletion of incomplete cases at the end of the course, the total number of participants amounted to 115 (50 women and 65 men). The number of participants in each group was: 39 for the treatment group (15 women and 24 men), 40 for the contrast group 1 (15 women and 25 men), and (c) 36 for the contrast group 2 (20 women and 16 men).
2.2 Measures

In order to measure the participants’ self-efficacy in vocabulary learning, a questionnaire, comprised of four items, was administered. The items were the same ones used in Mizumoto (2013), in which the validity and reliability of the scale were established. The participants responded on a six-point scale, from 1 (Not at all true of me) to 6 (Very true of me), according to the degree of perception on their learning process. The same questionnaire was administered three times at (a) Time 1: the beginning of the first semester, (b) Time 2: the end of the first semester, and (c) Time 3: the end of the second semester to investigate the changes in the trajectory of self-efficacy. Table 1 shows the descriptive statistics of self-efficacy at three measurement occasions (see Appendix A for the items).

In addition to the questionnaire, a vocabulary test was administered, as a measure of vocabulary knowledge (see Appendix B for the sample items). The test was made up of 60 items from the academic vocabulary section of Vocabulary Levels Test (Schmitt, 2000; Schmitt, Schmitt, & Clapham, 2001), modified by the author (Mizumoto, 2013). This test was administered as a pretest and a posttest to examine the effects of integrating a self-regulated learning approach into regular English courses (Table 2).

2.3 Procedures

The three groups of participants met once a week for a 90-minute class during a 15-week semester. The study lasted two semesters, spanning 30 classes in total (approximately eight months). All three classes used the same textbook, Focus on Vocabulary 1 (Schmitt, Schmitt, & Mann, 2011). At the beginning of each lesson,
only the treatment group received a handout, which contained (a) a space to write
the learner’s specific action plans to achieve their short-term goal by the next lesson
(i.e., goal setting), (b) a table describing “what is involved in knowing a word”
(Nation, 2001) to draw the learner’s attention to a variety of aspects (meaning,
form, and use) in learning a word, (c) a space to write the strategies they plan to use
to memorize the target vocabulary of the week, (d) a space to write a self-reflection
report about their learning, and (e) three self-efficacy rating scales to reflect on their
self-regulated learning. The cyclic self-regulative approach (Zimmerman, Bonner, &
Kovach, 1996) was used as a model for instruction.

The session always lasted 10–15 minutes of a 90-minute lesson. For the first
few lessons, the teacher, author of this article, described explicitly the key concepts
such as self-regulated learning, vocabulary-learning strategies, and metacognitive
strategies. The participants were encouraged to exchange their ideas and opinions
about the things they wrote down on their handout. This type of interaction was
included to help participants understand the different perspectives on vocabulary of
other participants.

2.4 Data analyses

All the analyses in this study were conducted using R version 2.14.2. To
address the research question of the current study, “Will self-efficacy in vocabulary
learning be enhanced by integrating a self-regulated learning approach?” A
multilevel analysis of change was employed. Multilevel model, also known by the
names such as hierarchical linear model, linear mixed model, mixed-effect model,
and random effects model, can be applied to longitudinal data analysis to
investigate change over time (specifically called growth curve model in such
application). The advantages of these newer statistical models over traditional
procedures such as ANOVA can be so great that Second Language Acquisition
(SLA) researchers have increasingly started using multilevel modeling (e.g., Kozaki
& Ross, 2011) and mixed-effect modeling (e.g., Ardasheva & Tretter, 2012;
Cunnings, 2012; Sonbul & Schmitt, 2013), depending on the purpose of the
research.

In addition to the longitudinal analysis of self-efficacy in vocabulary learning
data, gain scores of vocabulary test (i.e., posttest minus pretest) was submitted to
one-way ANOVA with a one between-subject factor (i.e., the type of intervention)
to further investigate the effects of integrating a self-regulated learning approach
into regular English courses. It should be noted that the result of this analysis is
identical with the interaction effect gained in a two-way ANOVA with a one
between-subject factor (intervention) and a one within-subject factor (pretest and
posttest). Following the one-way ANOVA, post hoc multiple comparison tests were
performed using the Tukey procedure.

3. Results and discussion

Table 3 is a summary of the results of multilevel analyses of change. Model A
is the unconditional means model, and it is the first step to confirm that it is
justifiable to employ the multilevel analysis (Singer & Willett, 2003). Especially, the
intraclass correlation coefficient ($\rho$) shows the relative magnitude of total variation, which is derived from the between-person variance component (Level 2). Estimation of $\rho$ can be obtained from the following equation:

$$\rho = \frac{\sigma_0^2}{\sigma_0^2 + \sigma_e^2}$$

For Model A, $\rho$ is 0.72, indicating large variation in self-efficacy can be explained with differences among individuals. This result warrants subsequent analyses with the multilevel modeling.

Model B is the unconditional growth model with time (i.e., Time 1, 2, and 3) as the only predictor. The result suggests that overall self-efficacy of the participants in the current study steadily increased with the slope of 0.16 ($\gamma_{10}$) from the initial intercept of 3.05 ($\gamma_{00}$). Model C includes intervention ($\gamma_{01}$ and $\gamma_{11}$) as a predictor of initial status and rate of change. Model D adds pretest ($\gamma_{02}$ and $\gamma_{12}$) to Model C to control for the effects of pretest on initial status and rate of change. The inclusion of the vocabulary pretest scores in the model was legitimate because self-efficacy and proficiency (i.e., vocabulary knowledge) would be related to each other. In fact, Model D showed the best goodness-of-fit indexes (the smaller the value, the better fit it is) among all the models. To improve the interpretability of the parameters, pretest scores were recentered on the sample means (Singer & Willett, 2003, p. 113). The parameters $\gamma_{11}$ and $\gamma_{11}$ in Model D indicate that self-efficacy among the three groups differs after controlling for the effects of pretest.

The final model (Model D) of the current study can be expressed as follows:

Level 1 (within-person) $Y_{ij} = \pi_{0i} + \pi_{1i}TIME_{ij} + e_{ij}$

Level 2 (between-person) $\pi_{0i} = \gamma_{00} + \gamma_{01}INTERVENTION + \gamma_{02}PRETEST + \zeta_{0i}$

$\pi_{1i} = \gamma_{10} + \gamma_{11}INTERVENTION + \gamma_{12}PRETEST + \zeta_{1i}$

where $i$ represents the learner and $j$ the measurement occasion. By using this equation and the fixed effects in Model D ($\gamma_{00}$, $\gamma_{01}$, $\gamma_{02}$, $\gamma_{10}$, $\gamma_{11}$, and $\gamma_{12}$), the predicted self-efficacy for each group can be obtained (displayed in Figure 1, bottom panel). As is evident from Figure 1, the treatment group showed a steady

increase in self-efficacy during the three measurement occasions. Both the contrast groups stayed almost the same during the period. This result, along with the result of the multilevel modeling, suggests that self-efficacy in vocabulary learning can be enhanced by integrating a self-regulated learning approach.

Table 4 presents a summary of the results of a one-way ANOVA of the gain scores of vocabulary test, and Table 5 the results of post hoc multiple comparison tests with the Tukey procedure. One-way ANOVAs confirmed that statistically significant differences were found in the gain scores of the vocabulary test for the three groups compared. The results of post hoc multiple comparison tests showed that statistically significant differences existed between the treatment group and the other two contrast groups. The result indicates that the treatment group exhibited a greater gain in their vocabulary knowledge than the other two contrast groups. These trajectories of change in vocabulary knowledge are in line with the patterns observed in self-efficacy (i.e., the treatment group showed a steady increase compared with the other two contrast groups).

Note. Refer to Table 2 for the gain score means and standard deviations.

Taken together, these results provide empirical evidence to answer the research question of the current study: “Will self-efficacy in vocabulary learning be enhanced by integrating a self-regulated learning approach?” That is, integrating a self-regulated learning approach in a regular class sessions will enhance self-efficacy in vocabulary learning. Furthermore, from the results of the gain score analyses in the vocabulary test, it would be reasonable to assume that the enhanced self-efficacy through a self-regulated learning approach may lead to a gain in vocabulary knowledge.

4 Conclusion

The current study is aimed at exploring the effects of integrating a self-regulated learning approach on self-efficacy with vocabulary learning. The findings
from the current longitudinal study suggest that through a self-regulated learning approach, it would be possible, for teachers and learners alike, to enhance self-efficacy, which in turn may contribute to the development of vocabulary knowledge.

The pedagogical implication of results of the current study relates to the importance of measuring self-efficacy as a measure of mastery in vocabulary learning. Thus, self-efficacy should be measured and teachers are encouraged to enhance it through the instruction of self-regulated learning or vocabulary learning strategies as part of the language-focused learning strand (Nation, 2007). With the enhancement of self-efficacy at its core, teachers can provide instructions for vocabulary learning strategies, or more encompassing concept self-regulated learning, to help the learners become more autonomous.

Acknowledgments
This research was made possible by a Grant-in-aid for Scientific Research (No. 24720276) from the Japan Society for the Promotion of Science. I would like to thank the anonymous reviewers of Vocabulary Learning & Instruction for their insightful comments and suggestions on the manuscript.
